I. Introduction

UDFCD & Stormwater Quality

The Urban Drainage and Flood Control District (UDFCD) was established by the Colorado legislature in 1969 for the purpose of assisting local governments in the Denver metropolitan area with multi-jurisdictional drainage and flood control problems. UDFCD monitors a number of stormwater Best Management Practice (BMP) sites in the Denver metropolitan area and plays a large role in stormwater quality improvement by way of research and promulgation of criteria. UDFCD samples inflow and outflow and collects data on rainfall and runoff at several BMP sites.

UCFCD's primary objectives are to:

- Determine the Event Mean Concentration (EMC) of different constituents that affect stormwater runoff.
- Assess the longer term performance of each BMP with regard to stormwater quality and runoff volume reduction.

Pervious Concrete at Lakewood Maintenance Facility

At the Lakewood City Shops maintenance buildings, UDFCD is monitoring pervious concrete. Pervious concrete is one of several different types of permeable pavement systems that are designed to infiltrate stormwater through the pavement surface. Permeable pavements are a common and important practice of Low Impact Development (LID). pervious concrete is a monolithically-poured pavement that has 15% to 21% of its volume as void. The voids within the concrete are achieved by eliminating the fine sand aggregate from the concrete mix. The voids provide the flow paths for rainwater from the surface of the pavement to the base course underlying it.

A view of the pervious concrete from the street is shown in Photograph 1.

Photograph 1. Pervious concrete at Lakewood Maintenance Facility

II. Site Description

Study Area

The pervious concrete and a reference site parking areas are located at 850 Parfet Street in a parking lot for City of Lakewood employees. UDFCD had previously monitored concrete grid pavement at this site. This was replaced with pervious concrete in 2005. An adjacent area of conventional asphalt pavement provides the reference site. The reference site is located in the same parking lot as the pervious concrete and is used to compare water quality and flow of the treated (pervious concrete) effluent to untreated (reference site) runoff. Both sites receive similar traffic loads, generally vehicles that arrive in the morning and leave at the end of the workday. The vicinity and location of the site are shown in Figures 1 and 2, respectively, with the reference site and the pervious concrete located in Figure 2. The area of pervious concrete is circled in red.

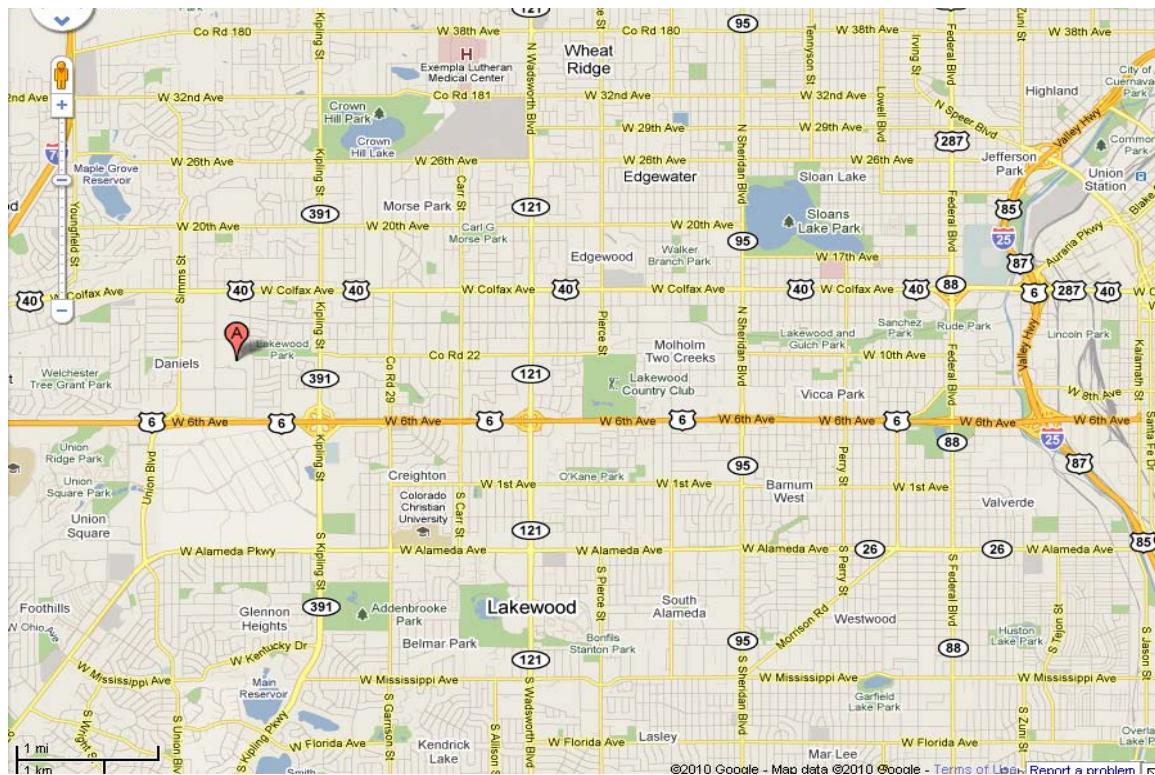

Figure 1. Vicinity Map

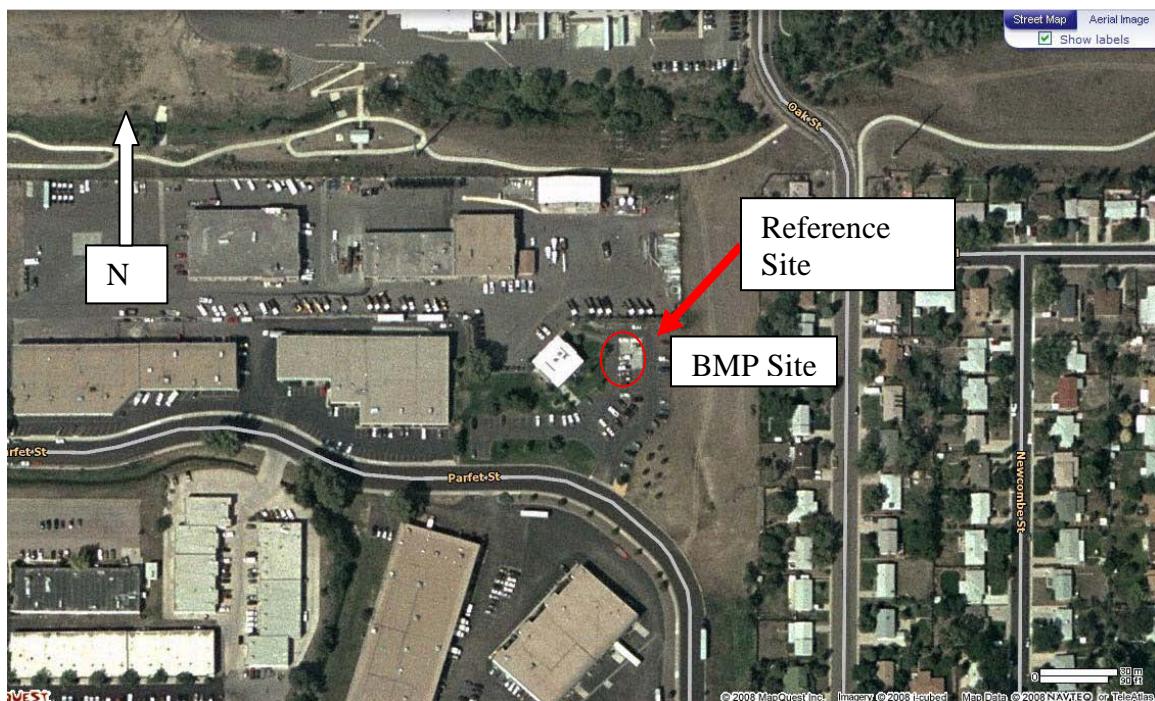

Figure 2. Location Map

Watershed

Tributary area to the pervious concrete is 100% impervious and stable. It consists of traditional asphalt and concrete pavement and is 9,050 square feet, of which 7,077 square feet is impervious tributary to the pervious concrete. A plan view of the reference site tributary is provided in Figure 3. Note that asphalt berms have been constructed in areas where the tributary delineation lines are not perpendicular to the contours. The area of the watershed for the reference site is 8,900 square feet. Stormwater runoff from the control watershed is collected in a sump catch basin at the northeast corner of the site. The run-on ratio of the tributary impervious area to the pervious concrete is 3.5:1, which exceeds the recommended ratio of 2:1 provided in Volume 3 of the Urban Storm Drainage Criteria Manual (USDCM).

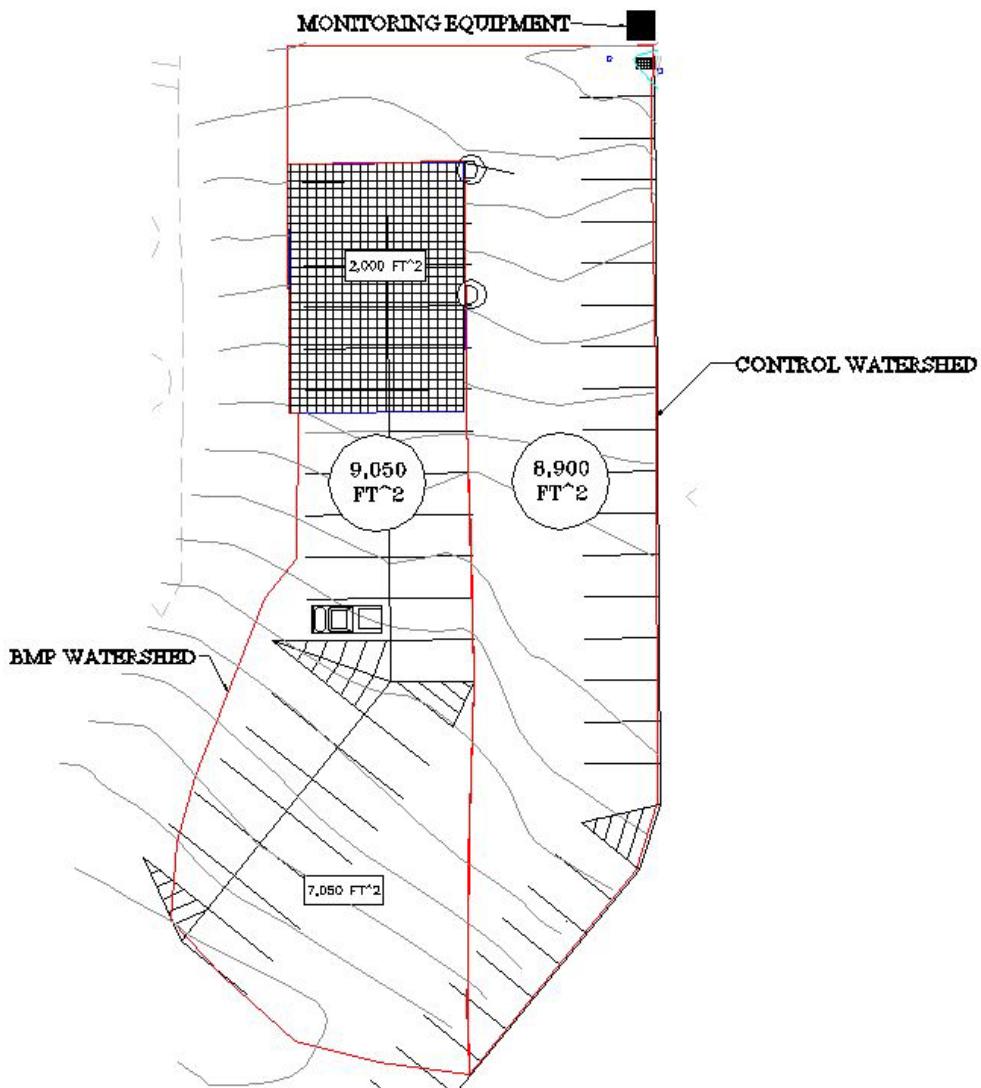

Figure 3. Plan of the Watersheds for the Pervious Concrete and Reference Site

III. Methods and Materials

Pervious Concrete Components

The pervious concrete is divided into two cells, an upslope cell on the south side of the pervious concrete and a downslope cell on the north side. There is a wall in the middle that divides the cells to maximize water volume entrapment. Underneath the concrete there is an overflow weir in the middle wall that is designed to convey overflow from the upslope cell into the downslope cell when the volume in the upslope cell is completely utilized. This also serves to ensure that runoff doesn't resurface or freeze in the wearing course. The design utilizes a "no-infiltration" section with an impermeable liner at the bottom and edges of the section. Figure 4 provides an isometric view of the pervious concrete layout. Figure 5 provides details for the collection wells that drain each cell independently. The outlets for each contain orifices to release the WQCV over approximately 6 hours.

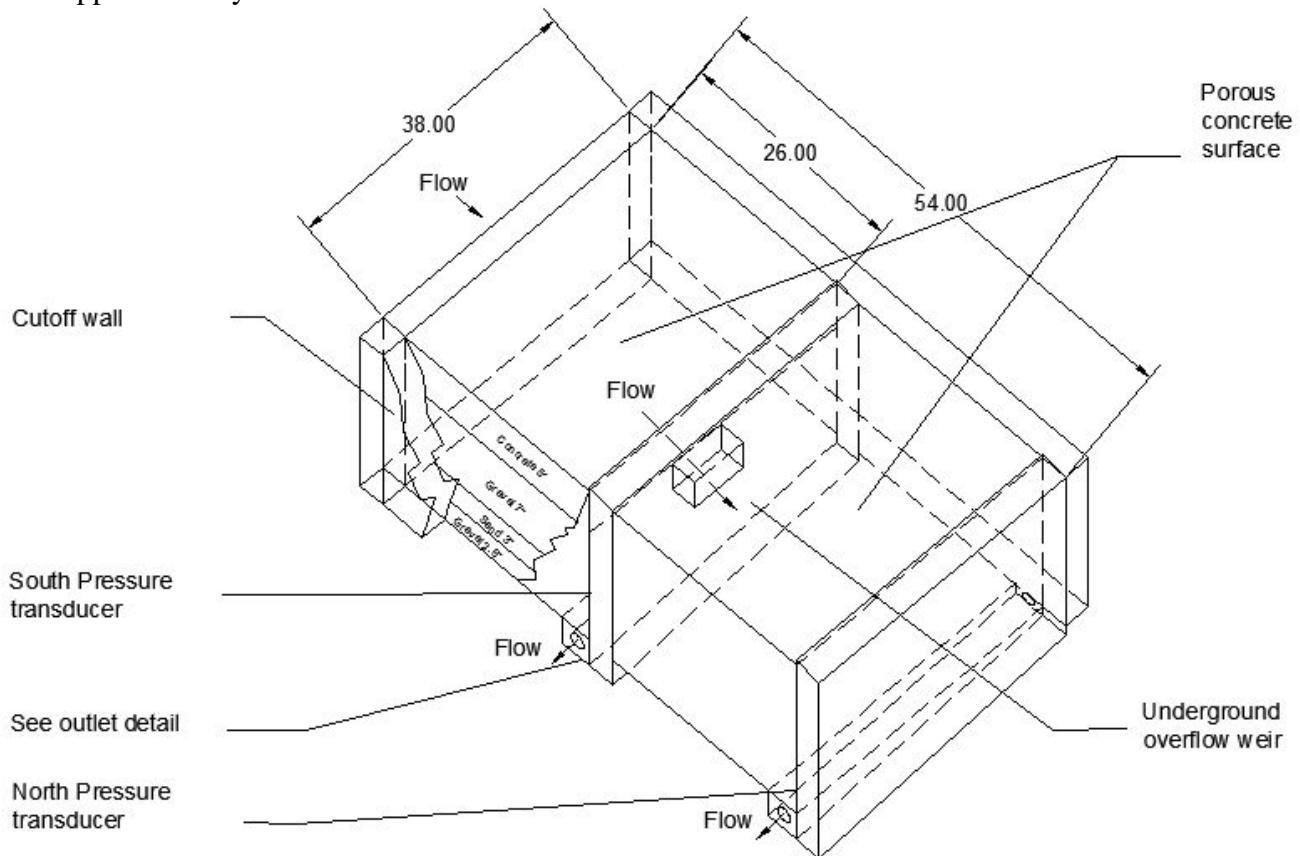

Figure 4. Isometric Plan of the pervious concrete

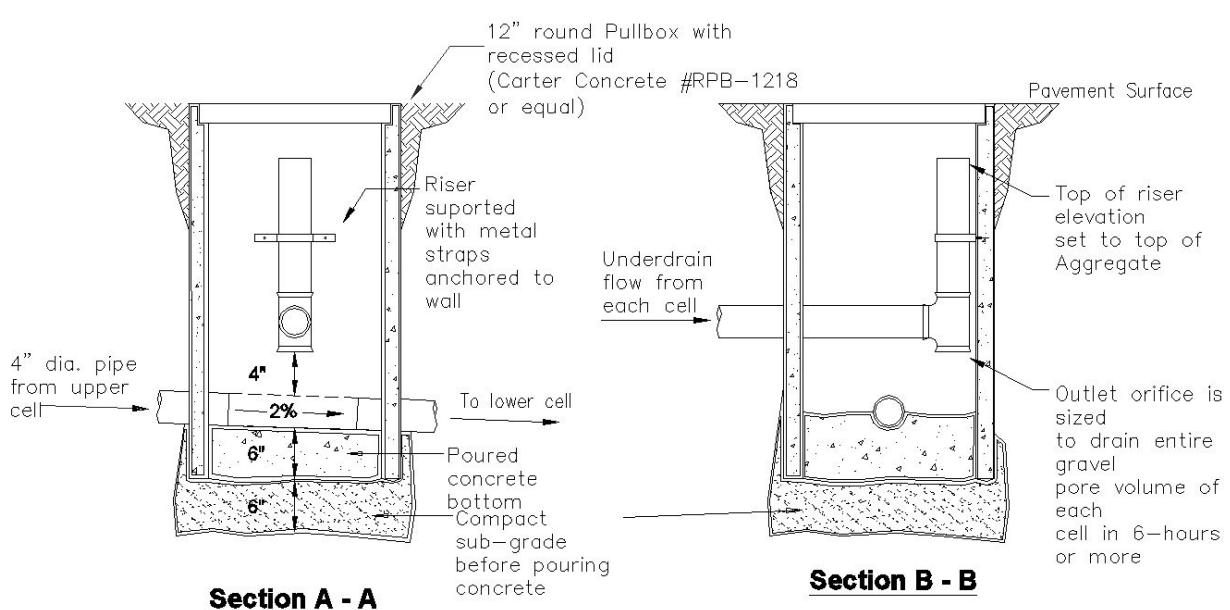

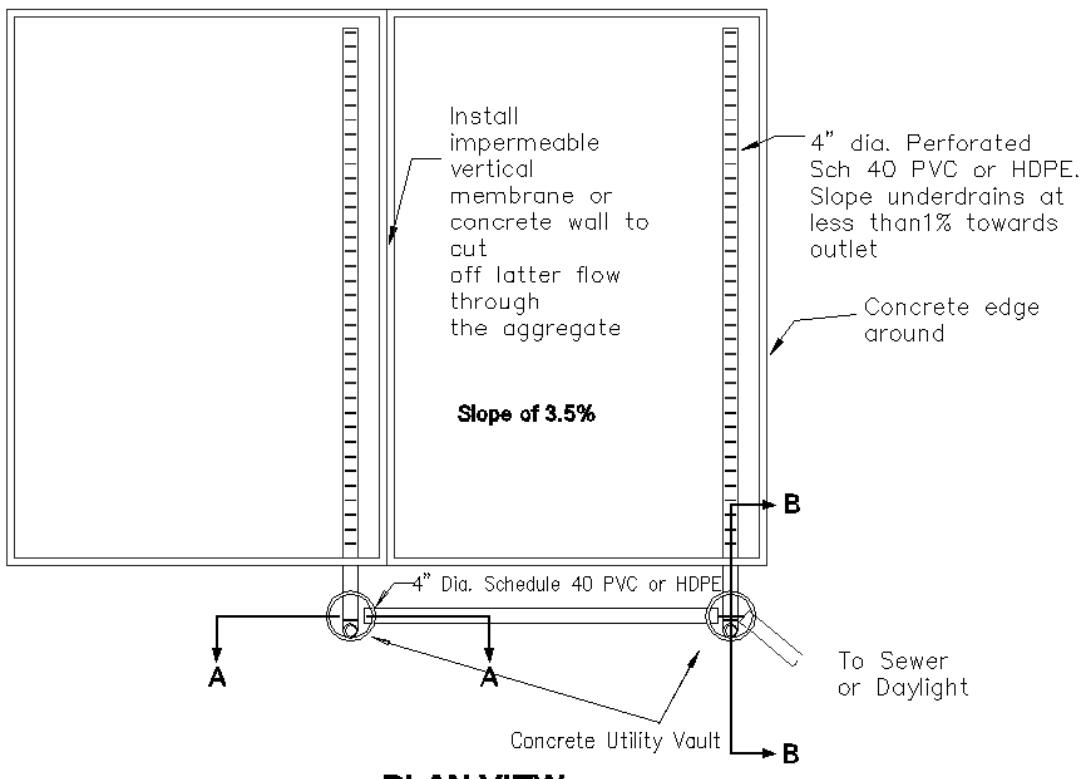

Figure 5. Plan and Sections Detailing Outlet Control

Both cells of the pervious concrete have two slightly different wearing courses. The east half of both cells utilizes AASHTO #67, a larger aggregate. The west side of each cell utilizes AASHTO #8, a smaller aggregate. The surfaces are shown in Photograph 2. In 2010 the AASHTO #8 aggregate course, which is the smaller of the two, began to ravel while the wearing course with larger aggregate remains undamaged. The section below the wearing course is consistent throughout the installation. It consists of a reservoir layer (large aggregate layer) and a sand filter layer. The reservoir layer beneath, immediately below the wearing course, provides structural support as well as stormwater storage volume. The filter layer provides improved water quality and fine particulate removal. At each lateral flow barrier, water is collected in a perforated pipe (underdrain) and is carried into a manhole. An impermeable membrane placed under the pavement section ensures that outflow samples can be collected and will not infiltrate into the subgrade. The outlet for each cell is designed to drain the gravel pore volume of each cell in approximately six hours. Figure 6 shows the volume available for storage in a sloping pavement. Finally the flows from each cell are combined and directed into a V-notch weir at the northeast corner of the site. The pervious concrete section is shown in Figure 7.

Level loggers have also been placed just upstream of the outlet for each cell. This provides the ability to monitor how quickly the section drains and if, over time, the sand filter layer becomes more limiting than the orifice.

Data Collection

All samples are tested for the following:

| Category | Constituent | Units | Detection Limits |
|------------|-------------------------|---------|------------------|
| Chemical: | Alkalinity | mg/L | 20 |
| | Chloride | mg/L | 1 |
| | Chemical Oxygen Demand | mg/L | 20 |
| | Conductivity | umho/cm | 0.1 |
| | Hardness | mg/L | 10 |
| | pH | | |
| | Total Organic Carbon | mg/L | 1 |
| Metal: | Dissolved Calcium | mg/L | 1 |
| | Dissolved Iron | mg/L | 0.05 |
| | Dissolved Magnesium | mg/L | 1 |
| | Dissolved Sodium | mg/L | 1 |
| | Dissolved Chromium | µg/L | 1 |
| | Dissolved Manganese | µg/L | 1 |
| | Dissolved Nickel | µg/L | 2 |
| | Dissolved Copper | µg/L | 5 |
| | Dissolved Zinc | µg/L | 1 |
| | Dissolved Selenium | µg/L | 0.2 |
| | Dissolved Silver | µg/L | 0.1 |
| | Dissolved Cadmium | µg/L | 1 |
| | Dissolved Lead | µg/L | 1 |
| | Total Beryllium | µg/L | 5 |
| | Total Chromium | µg/L | 1 |
| | Total Manganese | µg/L | 1 |
| | Total Nickel | µg/L | 2 |
| | Total Copper | µg/L | 20 |
| | Total Zinc | µg/L | 5 |
| Nutrients: | Total Arsenic | µg/L | 1 |
| | Total Selenium | µg/L | 5 |
| | Total Molybdenum | µg/L | 0.2 |
| | Total Silver | µg/L | 0.5 |
| | Total Cadmium | µg/L | 5 |
| | Total Antimony | µg/L | 5 |
| | Total Lead | µg/L | 5 |
| | Dissolved Phosphorus | mg/L | 1 |
| | Dissolved Potassium | mg/L | 0.1 |
| | Nitrite+Nitrate | mg/L | 0.01 |
| | Ortho-Phosphorus | mg/L | 0.005 |
| | Total Kjeldahl Nitrogen | mg/L | 0.3 |
| | Total Phosphorus | mg/L | 0.01 |
| Physical | Total Suspended Solids | mg/L | 1 |

UDFCD has been collecting water quality and flow data from this site since 2005. Automatic samplers (ISCO model 6712) are used to record flow data and pull samples from both the pervious concrete and the reference site throughout the runoff event. The sampling equipment is stored in a shed near the outlet works. Rainfall is measured to 0.01 inches by a ISCO 674 tipping rain gauge on top of the shed, shown in Photograph 3. The rain gauge signals the ISCO samplers inside the shed to begin sampling when it detects over 0.08 inches of rainfall in two hours and a volume of ten cubic feet passes through the outlet.

The underdrain for the pervious concrete site drains into a 4-inch PVC pipe, which outlets to the 30 degree V-notch weir shown on the left side of Photograph 4. Just upstream of the weir an ISCO 720 pressure transducer is used to measure head over time for flow and volume calculations. Samples are also pulled at this location. A single sample of 500 mL is pulled each time ten cubic feet pass the weir. All samples are pulled into a single 10 L bottle located inside the sampler.

The reference site drains to an inlet that discharges through an H-flume at the reference site. The depth of the water going through the H-flume is measured by an ISCO 720 pressure transducer for flow and volume calculations. Similar to the pervious concrete site, a single sample of 500 mL is pulled each time 10 cubic feet pass the H-flume. All samples are pulled into a single 10 L bottle located inside the sampler.

Photograph 3. The sampling shed with rain gauge.

Photograph 4. The V-notch weir for the pervious concrete (left), and the H-flume weir for the reference site (right), with stilling wells in the background.

Maintenance Practices

Left unmaintained this type of pavement will lose infiltration capacity resulting in a smaller volume of water being treated. According to USDCM Volume 3, a regenerative air or vacuum sweeper should be used approximately twice per year to maintain infiltration rates. This should be done on a warm dry day for best results. The frequency is site specific and inspections of the pavement may show that a different frequency of sweeping is more appropriate.

This site was not maintained to the above standards and was not vacuumed until 2011. Although the pavement consistently produced samples, it became relatively clogged over time. In 2011 the pavement was vacuumed with a vacuum sweeper truck; however, this was just following a rain event and conditions were wet. A second attempt to vacuum the pavement using small amounts of water and a hand vacuum were mildly successful in producing a noticeable increase in infiltration rates. In 2010, it was discovered that was a separation between the wearing course and the wall separating the cells allowing water to bypass the pervious concrete; however, it still passes through the sand filter and produces a sample.

IV. Results and Discussion

Outflow Volume Reduction

Based on the inconsistencies observed with reference site and BMP flow and volume measurements as well as inconsistencies between reference site volume compared to calculated volume (based on rainfall), a low level of accuracy in these values is assumed.

The volume data includes 65 paired sets. Volume per unit tributary area was compared between the reference site and the BMP. A volume based on rainfall was also calculated for comparison with the reference site volume. Fifty of the 65 sets showed a reduction from the reference site to the BMP. Including all data sets and looking at total volume values, a reduction of 24% was

calculated between calculated volume and measured volume at the BMP and a reduction of 38% was calculated between measured flow at the reference site and measured flow at the BMP.

Flow data is provided in Tables 1 through 7. Figure 10 provides a comparison for each paired set of data.

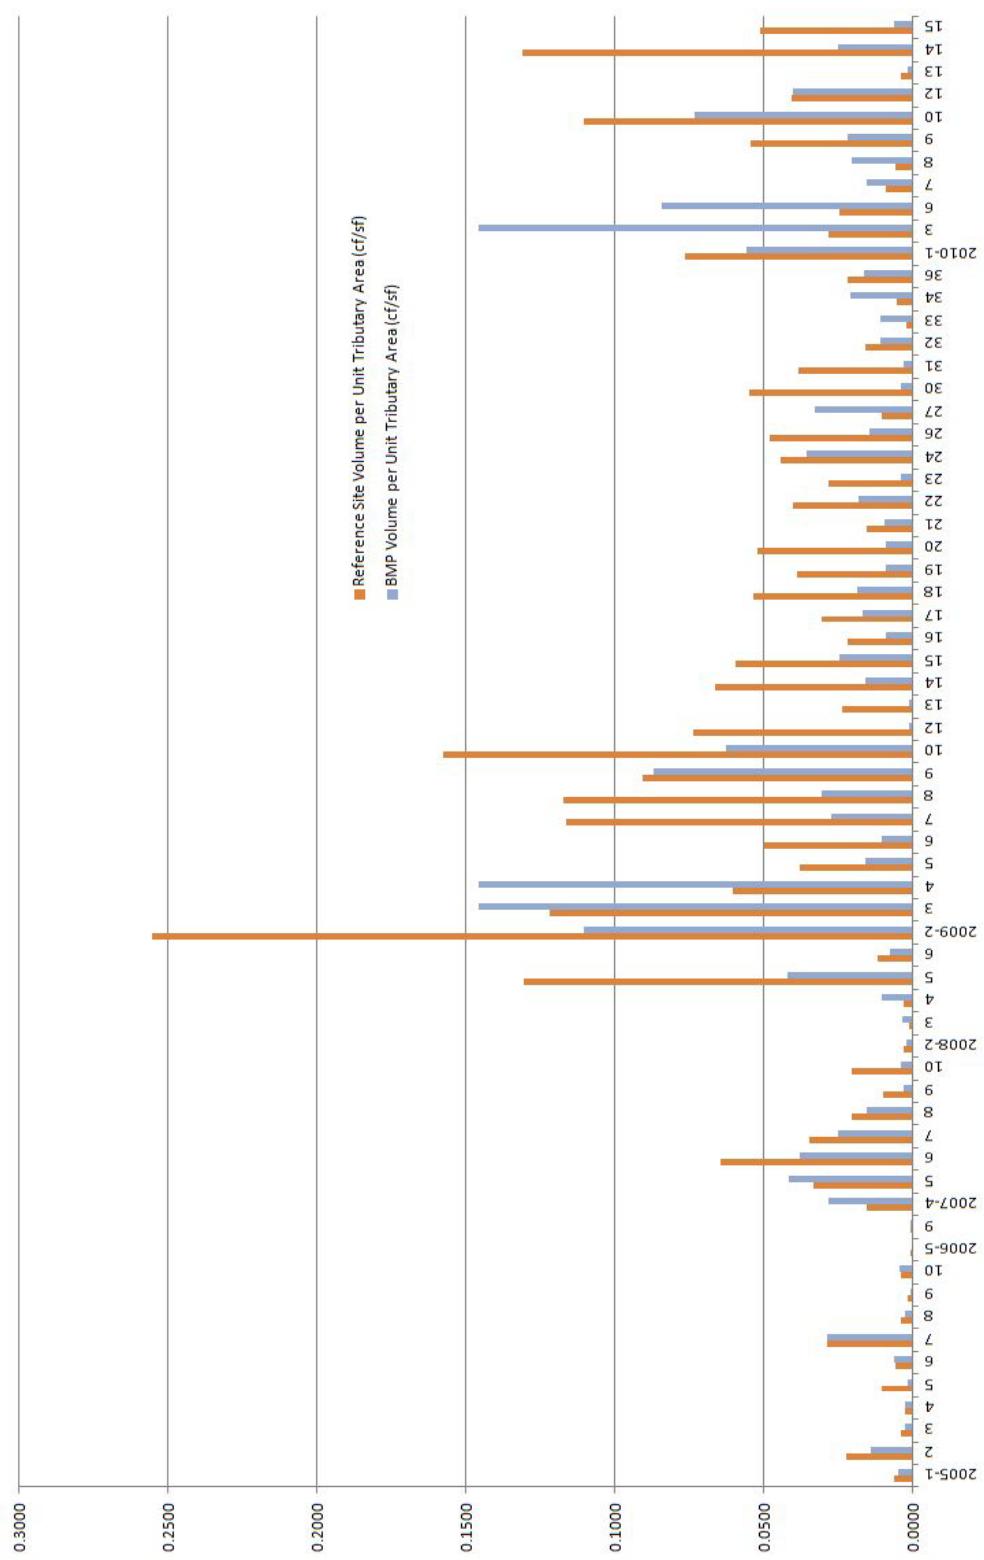

Figure 10. Measured Volume of Reference Site and BMP

Impact on Water Quality

To conduct the water quality analysis, t-tests were performed to compare the means for the reference site and the BMP for each constituent. Data was analyzed year by year and then combined and analyzed for all years. A non-parametric Wilcoxon signed-rank tests were performed in addition to parametric paired t-tests and two sample t-tests since some of the data did not fit a normal distribution. The p-values generated for each of the constituents ($\alpha=0.05$) are provided in Tables A-1 through A-7 of Appendix A. A summary table showing data sets with significant differences and also indicating whether constituent values were higher at the reference outlet or the BMP outlet is provided in Table 8. The values that were significant, below the alpha level of 0.05, are in bold. It is also important to note that in cases where certain constituents were not detected in a sample, we used zero as a number for our analysis.

The results of the statistical analysis show significant differences between the reference site and the BMP. About half of the constituents were in lower concentrations at the pervious concrete and half were in higher concentrations. Except for Total Copper and Total Manganese, none of the constituents that were in a significantly higher concentration in effluent from the reference site or BMP site in one year were significantly lower for another year. Total Copper data show a decrease in concentration in the BMP effluent of the 5 years of study. It is significantly high in BMP effluent in 2006 and 2007 and significantly lower in the BMP effluent in 2010. With the exception of 2005 data, Total Manganese also shows a decline in concentration over time. It is significantly higher at the BMP outlet in 2006 and significantly lower in 2010.

ANOVA and Tukey multi-comparison tests were also used to analyze the difference in variation between and within samples for each year, and to analyze pairwise differences in the mean for each year, respectively. The results of these tests are provided in Tables A-8 and A-9 of Appendix A. These tests were only performed for Total Suspended Solids, Total Phosphorus, and all total metals. The purpose of these tests was to investigate the relationship of these constituents, which have been known to adsorb to Total Suspended Solids, and can sometimes be removed through filtration of Total Suspended Solids. The values that were significant, below the alpha level of 0.05, are in bold. Generally speaking, the low number of significant values in the BMP effluent and high number at the reference site suggest that this BMP provides consistent effluent values of Total Suspended Solids and the constituents that adsorb to it. Total Selenium, Total Nickel, Total Cadmium, and Total Chromium were the exception; however, it should be noted that there was a lack of data for Total Selenium.

Tables with all the water quality data (by year) are provided in Tables 9 through 16 with descriptive statistics for each year provided in Tables 17 through 52. Box-and-whisker plots for each constituent for combined year data are provided in Figures 13-47.

V. Conclusion

Although the wearing course of the pavement has become relatively clogged due to lack of maintenance, runoff is also enters the pavement at the pavement interface with lateral barrier walls and flows through the sand filter layer into the underdrain. Efforts to increase infiltration should continue.

Calculations show that this BMP may provide volume reduction between 24 to 38%; however, due to inconsistencies observed in the data, a low level of accuracy in this value is assumed.

Water quality data shows a high number of statistically significant differences between reference and BMP sites. Most of the data was highly significant, about half of the constituents were in lower concentrations at the pervious concrete and half were in higher concentrations. Except for Total Copper and Total Manganese, none of the constituents that were in a significantly higher concentration in effluent from the reference site or BMP site in one year were significantly lower for another year. Total Copper data show a decrease in concentration in the BMP effluent of the 5 years of study. It is significantly high in BMP effluent in 2006 and 2007 and significantly lower in the BMP effluent in 2010. With the exception of 2005 data, Total Manganese also shows a decline in concentration over time. It is significantly higher at the BMP outlet in 2006 and significantly lower in 2010. Based on this study, this BMP provides significant reductions in several targeted constituents including Total Suspended Solids, Total Phosphorus, Total Kjeldahl Nitrogen, Chemical Oxygen Demand, and several dissolved and total metals. The most problematic water quality issue may be the increase in pH observed in the BMP effluent, with both mean and median values for combined years data above nine and no downward trend of this constituent.

Water quality constituent concentrations can be compared with other permeable pavement studies found in the International Stormwater BMP database, as summarized in Table 53, which is adapted from Table 2-2 in Volume 3 of the USDCM. The database values are fairly consistent with those produced by this study. Water quality data for the reference site can also be compared to commercial runoff data from the Denver Regional Urban Runoff Program (DRURP), as summarized in Table 54. The commercial DRURP data and the reference site data are also fairly consistent.

Table 53. Comparison of Median Constituents for the Pervious Concrete at Lakewood Maintenance Shops and the International Stormwater BMP Database

| | Lakewood Shops Pervious Concrete | | International Stormwater BMP Database | |
|---|-------------------------------------|------------------------|---|---------------------------|
| Water Quality Constituent | Reference Median Value | BMP Median Value | Inlet Median Value | Outlet Median Value |
| Total Phosphorus (mg/L) | 0.155 | 0.1 | 0.12 | 0.13 |
| Total Suspended Solids (mg/L) | 64 | 28.5 | 23.5 | 29.1 |
